Instructions

1. **Which of the following statements concerning the prevalence rates of the fear of flying in different countries is accurate?** 1 / 1 point

○ The prevalence rates do not differ by a country's income.

● The prevalence rates are higher in middle and higher income countries than lower income countries.

○ The prevalence rates are lower in middle and higher income countries than lower income countries.

✓ **Nice work**

The prevalence rates are higher in middle and higher income countries and lower in lower income countries (Wardenaar et al., 2017).

2. **How do evolutionary psychologists explain why specific phobias are more common for potentially dangerous animals, such as spiders and snakes, than for firearms?** 1 / 1 point

○ Observational learning

● Biological preparedness

○ Cultural tradition

○ Political affiliation

✓ **Nice work**

Evolutionary psychologists assert that ancestral humans who developed fears of lethal animals and situations were more likely to survive and pass their genes onto future generations. This passing on of their genes led to the inherited trait of a bias toward fearing life threatening animals and situations, which was labeled as biological preparedness.

3. **In classical conditioning, an automatic response that does not require learning is called a** 0 / 1 point

○ conditioned response.

○ unconditioned response.

● unconditioned stimulus.

○ neutral stimulus.

Try again

4. **Once it is paired with an unconditioned stimulus, a neutral stimulus is called a** 1 / 1 point

○ Unconditioned stimulus

○ Neutral stimulus

○ Unconditioned response

● Conditioned stimulus

✓ **Nice work**

When a neutral stimulus (NS) is paired with an unconditioned stimulus (UCS), it starts to produce the same response as the unconditioned stimulus (UCS); this response is called the conditioned response (CR). The neutral stimulus (NS) then becomes known as the conditioned stimulus (CS), as it now produces a response because it is associated with the unconditioned stimulus (UCS).

5. **If a person is able to escape the fearful experience of seeing a phobic stimulus, their avoidance behavior is reinforced and they are likely to continue avoiding the stimulus. If a person has a dog phobia, the person will continue to avoid dogs to avoid the feeling of fear. But because they never get the opportunity to have a pleasant interaction with a dog, their phobia persists. What type of learning does this represent?** 1 / 1 point

○ Classical conditioning

● Operant conditioning

○ Biological preparedness

○ Observational learning

✓ **Nice work**

Operant conditioning is a type of learning in which a person associates their behavior with its consequences, in a process called reinforcement. With one type of reinforcement, negative reinforcement, people are likely to repeat behaviors that allow them to avoid or escape from an unpleasant stimulus.

6. **The acquisition of information, skills, or behaviors through direct instruction is called** 1 / 1 point

○ classical conditioning.

● observational learning.

○ operant conditioning.

✓ **Nice work**

Observational learning is the acquisition of information, skills, or behavior through watching the performance of others, either directly or via such media as films and videos. The observational learning of a fear response can occur by observing another individual's distress when faced with a fear-inducing stimulus.
